

**21<sup>th</sup> Section Oligopoly (Version 2)**

Oligopoly refers to the situation where the number of sellers in the market is small; more crucially the sellers can affect price either by setting it directly or through output produced. In this class we will focus our attention on the special case of duopoly, the situation where there are two sellers.

In all the following cases let the inverse demand be  $P_D(Q) = a - bQ$ , where  $Q = q_1 + q_2$  is the total output. We shall assume that the sellers have identical marginal cost  $= c$ .

**I. Cournot**

Each seller chooses its output taking opponent's output as given. Price determined by (inverse) demand.

---

Quantity:	$q_1^* = q_2^* = \frac{a - c}{3b}$
Price:	$p^* = P_D(q_1^* + q_2^*)$

---

**Output** in a Cournot setting is lower than output in a perfectly competitive market but higher than monopoly.

**Price** is lower than monopoly but higher than competitive market

**Total Profit** is lower than monopoly but higher than competitive market, which gives zero profit

**II. Bertrand**

Each seller chooses its price taking opponent's price as given. Quantity determined by demand. Here we have a price war, resulting in perfectly competitive price.

---

Quantity:	$Q^*$ given by $P_D(Q^*) = c$ Any combination of $q_1 + q_2 = Q^*$ is solution
Price:	$p^* = c$

---

**Output** and **Price** are the same as competitive market.

**Profit** is zero as in competitive market.

### III. Stackelberg

One seller gets to pick its quantity before the other. The main idea is that the seller who moves first has an advantage—it can take into consideration the other seller's response into consideration. The seller who moves later acts identically to a Cournot competitor; it takes the output of the first player as given when it gets to choose its own output.

---

$$\begin{array}{l} \text{Quantity:} \\ \text{Price:} \end{array} \quad \begin{array}{l} q_1^* = \frac{a-c}{2b} \\ q_2^* = \frac{a-c}{4b} \\ p^* = P_D(q_1^* + q_2^*) \end{array}$$

---

**Individual Output** for Seller 1 is higher than Cournot and lower for Seller 2.  
**Total Output** is higher than Cournot and monopoly but lower than competitive market.

**Price** is lower than Cournot and monopoly but higher than competitive market

**Individual Profit** is higher than Cournot for Seller 1 but lower for Seller 2.

**Total Profit** is lower than Cournot and monopoly but higher than competitive market.

### IV. Detailed example

#### Market Setting

$$\begin{aligned} P_D(Q) &= 30 - 2Q \\ c &= 4 \end{aligned}$$

#### Cournot

Seller 1 solves

$$\begin{aligned} &= \max_{q_1} \{ \pi_1 \} \\ &= \max_{q_1} \{ P_D(q_1 + q_2) \cdot q_1 - c \cdot q_1 \} \\ &= \max_{q_1} \{ [30 - 2(q_1 + q_2)] \cdot q_1 - 4 \cdot q_1 \} \end{aligned}$$

First order conditions:

$$\begin{aligned} \frac{d\pi_1}{dq_1} &= 0 \\ \frac{d}{dq} \{ [30 - 2(q_1 + q_2)] \cdot q_1 - 4 \cdot q_1 \} &= 0 \\ 30 - 4q_1 - 2q_2 - 4 &= 0 \\ q_1 &= \frac{30 - 2q_2 - 4}{4} \end{aligned}$$

Since the two sellers are identical in all ways, we have

$$q_2 = \frac{30 - 2q_1 - 4}{4}$$

Substituting the formula for  $q_2$  into  $q_1$ ,

$$q_1 = \frac{1}{4} \left[ 30 - 2 \left( \frac{30 - 2q_1 - 4}{4} \right) - 4 \right]$$

$$4q_1 = 30 - 15 + q_1 + 2 - 4$$

$$q_1 = \frac{13}{3}$$

Since the sellers are identical we have  $q_2 = \frac{13}{3}$

Verify that the formula on the first page is correct:  $\frac{a-c}{3b} = \frac{30-4}{3 \cdot 2} = \frac{13}{3}$

$$\text{Price: } P_D(q_1 + q_2) = 30 - 2(q_1 + q_2) = 30 - 2 \left( \frac{13}{3} + \frac{13}{3} \right) = \frac{38}{3}$$

### Bertrand

$$P_D(Q) = c$$

$$30 - 2Q = 4$$

$$Q = 13$$

$$\text{so } q_1 + q_2 = Q = 13$$

Price equals marginal cost = 4

### Stackelberg

Always solve *first* the seller that moves *last*—this method is called *backward induction*.

Seller 2's choice is exactly the same as in the Cournot case since  $q_1$  has already been decided by Seller 1 when Seller 2 gets to choose. So from the Cournot case we know

$$q_2 = \frac{30 - 2q_1 - 4}{4}$$

Taking this into account, Seller 1 solves

$$= \max_{q_1} \{ \pi_1 \}$$

$$= \max_{q_1} \{ P_D(q_1 + q_2) \cdot q_1 - c \cdot q_1 \}$$

$$= \max_{q_1} \left\{ \left[ 30 - 2 \left( q_1 + \frac{30 - 2q_1 - 4}{4} \right) \right] \cdot q_1 - 4 \cdot q_1 \right\}$$

First order condition:

$$\frac{d}{dq_1} \left\{ \left[ 30 - 2 \left( q_1 + \frac{30 - 2q_1 - 4}{4} \right) \right] \cdot q_1 - 4 \cdot q_1 \right\} = 0$$

$$30 - 4q_1 - \frac{30}{2} + \frac{4}{2}q_1 + \frac{4}{2} - 4 = 0$$

$$q_1 = \frac{30 - 30/2 - 2}{2}$$

$$= \frac{13}{2}$$

Substitute this into the formula for  $q_2$  gives  $q_2 = \frac{30 - 2(13/2) - 4}{4} = \frac{13}{4}$

Which are exactly what the formulas give us.

$$\text{Price is } P_D(q_1 + q_2) = 30 - 2(q_1 + q_2) = 30 - \left( \frac{13}{2} + \frac{13}{4} \right) = \frac{81}{4}$$
